ABSTRACT

This paper examines the capacities of smallholders in Nicaragua to exploit new linkages to certified coffee markets following the coffee crisis. Data on livelihood assets were collected from 292 households, which were clustered to test how differences in outcomes (asset building) reflect variations in initial asset endowments. The results suggest that most households built particular elements of their asset base and increased their resilience to future shocks. However, households struggled to make effective use of the gains for intensifying their livelihoods. Of the least-endowed households, few made investments in the scale or productivity of coffee, and most continued to depend heavily on subsistence production and seasonal off-farm income for survival. In conclusion, improved market access alone, even under relatively favorable market conditions and with considerable external support, will have uncertain impacts on rural poverty if the underlying constraints on household assets and investments are not addressed concurrently.

Introduction

Intensify, innovate, and specialize — this was the essential message for governments and donors looking to address the devastations of the coffee crisis in Central America and other coffee-producing regions. Between 1999 and 2005 prices paid for green coffee did not allow producers in Central America to cover their variable costs of production (JADB, 2002). Most smallholders reduced investment in coffee productivity, while others abandoned coffee plantations altogether, or uprooted plantations in favor of basic grains and other crops (Castro et al., 2004). Influential publications argued that smallholders had limited opportunities to increase their share of the benefits from trade in commodity coffee markets, given that the overwhelming proportion of economic returns flowed to actors in developed countries (Oxfam, 2001; Ponte, 2002; Gibbon and Ponte, 2005).

Consensus emerged that support for building smallholders’ links to specialty coffee markets, including those for certified fair-trade and organic coffee, would improve the prospects for increasing their resilience to future shocks. However, households struggled to make effective use of the gains for intensifying their livelihoods. Of the least-endowed households, few made investments in the scale or productivity of coffee, and most continued to depend heavily on subsistence production and seasonal off-farm income for survival. In conclusion, improved market access alone, even under relatively favorable market conditions and with considerable external support, will have uncertain impacts on rural poverty if the underlying constraints on household assets and investments are not addressed concurrently.

While NGOs, donors, and development agencies have maintained their enthusiasm for facilitating smallholder links to higher-value markets (Devaney, 2011), few value chain studies or
assessments of value chain interventions have explicitly documented the impact of improved market access on poverty, gender, or the environment (Bolwig et al., 2010; Stoian et al., 2012). Project assessments generally have relied on only a few generic impact indicators (e.g., output per acre, size of holding, and income gained) and thus have provided limited understanding of the determinants of household participation and the benefits across different types of households (e.g., Zandniapour et al., 2004; Humphrey and Navas-Alemán, 2010). As a result, policy makers and development practitioners have inadequate guidance for the design of the necessarily complex interventions that seek to help farmers benefit more from their linkages with higher-value markets.

Deeper insights into how smallholders benefit from linkages to higher-value markets can be obtained by adopting a livelihoods perspective, with special emphasis on households’ assets and the ability of households to build their endowments over time. In this paper, we undertake an analysis of household asset building in order to explore how differences in market participation reflect variations in households’ endowments of livelihood assets, namely natural, human, social, physical, and financial capitals. We consider:

- initial asset endowments of producing households,
- the contribution of development interventions to household asset building,
- how initial asset endowments and subsequent household changes determine smallholders’ participation in high-value export markets.

Section ‘An asset building framework’ describes the asset-building framework. Section ‘Case study background’ provides contextual information on the case study in Nicaragua. Section ‘Study design and methods’ discusses the methods used for data collection. Section ‘Changes in assets of coffee producing households’ presents the results on asset changes by coffee-producing households. In the final section, we discuss the implications of the findings for the design of development interventions aimed at linking smallholders to higher-value food markets.

An asset building framework

Poverty debates reflect a growing interest in the importance of assets for understanding poor people’s ability to respond to shortages and shocks and generate future income and consumption (e.g., Moser, 1998; Rakodi, 1999; Anderson, 2012). Economists have argued that a focus on assets provides a better option for understanding the underlying causes and the dynamics of poverty than a focus on income or consumption variables alone (e.g., Birdsall and Londono, 1997; de Janvry and Sadoulet, 2000). Carter and Barrett’s (2006) theoretical work on asset thresholds and poverty traps drew attention to how insufficient access to assets jeopardizes the long-term ability of households to pull themselves out of poverty. An understanding of asset endowments and interactions forms a core element of the frameworks for livelihood conceptualization and analysis (e.g., Ellis, 2000; Carney, 1998).

Academic discourse on the links between poverty reduction and access to higher-value markets suggests that the poorest smallholders often have too few assets to effectively participate over time. However, such insights into the roles of assets in shaping rural livelihoods have yet to translate into the design and assessment of interventions for linking smallholders to higher-value markets (Stoian et al., 2012). For example, the various methodologies for designing strategies that better link smallholders to markets pay little attention to households’ capacities, needs, and circumstances, thus making the implicit assumptions that (1) households have sufficient assets to effectively participate in higher-value markets, (2) do not face substantial trade-offs when using these assets, and (3) are able to assume higher risks for their investments (Donovan et al., 2013). Making such assumptions reduces the complexity for methodological implementation but runs the risk of formulating intervention strategies that provide limited long-term benefit to the rural poor.

More effective policies, programmes and projects for linking smallholders to globalizing food markets will require that key aspects of the development challenge be addressed in formal tools and frameworks. The framework presented here stresses the relationships between a household’s endowment of livelihood assets and its ability to engage in various livelihood activities (Fig. 1). Livelihood assets, namely natural, physical, social, financial, and human capitals, may be individual or collectively owned. These are built up through returns from market activities, remittances and inheritances, and inputs and services provided by NGOs and other external actors. Variations in asset accumulation may be explained, in part, by variations in the overall political, legal, and institutional context that shapes the decisions of producers and buyers. The stronger a household’s asset base, the greater is its ability to expand and intensify livelihood activities and thus benefit from links with more demanding markets.

Households maintain different types of commercial relations with buyers linked to local, national, and international food markets. In addition, households may engage in seasonal and year-round labor provision. Investments in household labor and financial resources and returns to those investments vary according to the market and over time. To the extent that new (more intensive) market linkages require new (increased) investments, trade-offs are likely between assets and among activities required to implement other livelihood activities, including subsistence production. Opportunities to reduce the costs and risks related to market investments may originate from collective enterprises, other buyers, and nonmarket actors (e.g., NGOs and government agencies).

This framework suggests that the design of pro-poor interventions in value chains must progress beyond the categorization of the types of capital to identify priorities for policy and interventions supporting asset building. Such prioritization should relate poor peoples’ access to different types of assets to the functions of those assets within changing and dynamic livelihood strategies, identifying the most effective livelihood development paths and the changing roles of different assets within those paths. The framework and methodological approach used here enables a systematic analysis of asset endowments and the varied livelihood strategies of the poor. It will help policymakers assess whether access to new or higher-value food markets will help households climb out of poverty, and address questions such as: Which households are more able to build their asset bases? How are assets built up over time? Which households are best able to invest in new or more intensive market linkages?

Case study background

Among agricultural products exported by Nicaragua, coffee is the most important, accounting for 37% of the total value of agricultural exports in 2008 (CEPAL, 2009). Nicaragua’s average coffee productivity, at 672 kg/ha (green coffee), makes it the least efficient producer in Central America, at roughly 50% of the productivity of Costa Rica and 40% of the productivity of Guatemala (Varangis et al., 2003). There are about 48,000 coffee farmers in Nicaragua, 80% of whom are producers with less than 3.5 ha under cultivation (Flores et al., 2002). Despite the large number of smallholders, farms larger than 3.5 ha produce more than 85% of
the Nicaraguan coffee harvest due to higher intensity of management and better access to purchased inputs. In general, coffee producers are better-off than the landless or those who produce basic grains and tubers mainly for subsistence. That said, the poorest of coffee farmers often lack resources for coffee production and basic living expenses and are vulnerable to negative changes in output and input prices, production risks and other shocks.

The research examined asset building by smallholders in north-central Nicaragua who were linked to certified fair-trade and organic coffee markets through the cooperative Soppexcca. Soppexcca has roughly 500 members. It emerged in 2001 from the ashes of its predecessor cooperative, which dissolved due to unpaid debts owed to international coffee buyers. Soppexcca’s membership more than doubled during the coffee crisis, as smallholders sought credit and higher coffee prices. In addition to providing access to certified markets, Soppexcca offers annual credit for coffee production, multiyear credit for strategic coffee-related investments, technical assistance for increasing coffee productivity and reducing environmental impacts of coffee production, and some forms of social protection. In 2009, all of Soppexcca’s coffee exports were fair-trade certified, and approximately 15% were certified for both fair trade and organic. Since its beginnings, Soppexcca has maintained strong ties with a small group of European coffee buyers. Recently, the cooperative has forged ties with U.S. coffee buyers.

Soppexcca, like other relatively large and well established cooperatives in Nicaragua, maintains close links with NGOs and development projects. Between 2003 and 2009, Soppexcca received about US$2.1 million from NGOs and development projects to build its infrastructure, strengthen its internal organization, and expand its service offer to members. Soppexcca maintains links to alternative lending institutions for access to low-cost credit for infrastructure development and the purchase of coffee from its members. In addition, Soppexcca receives support from coffee buyers in the form of fair-trade contracts (with social premium and floor prices) and zero-interest credit for purchase of coffee from its members. On average, in 2009, buyers offered Soppexcca prices that exceeded by 5–15% those established by fair-trade standards.

Study design and methods

Data collection focused on identifying changes in endowments of livelihood assets among coffee-producing households affiliated with Soppexcca during the four-year period between 2005–2006 and 2008–2009. Quantitative and qualitative data were collected to understand the changes in assets, and qualitative information was used to understand the relevance of and the reasons for the changes. Feasibility of empirical research and the tractability of analysis required a focus on specific elements of the five livelihood assets rather than undertake a comprehensive analysis of all asset concepts. After exploratory and participatory research among producers to validate asset concepts and methodology, the most important asset changes were assessed using the following set of indicators:

- **Natural capital**: access to land and area under coffee production, land tenure arrangements, access to fertilizers (proxy for soil fertility), and waste management.
- **Human capital**: management skills in coffee production, ability to participate in cooperative governance.
- **Social capital**: linkages and reciprocity in relationships with coffee buyers.
- **Physical capital**: capital for production and processing.
- **Financial capital**: access to credit, income benefit from coffee sales to Soppexcca.

In most cases, what we observed and measured provided a partial understanding of the five assets and their relevance for livelihood strategies. This is especially true in the case of social capital, the concept of which admittedly has been much contested (e.g., Fine, 1999). In research on smallholders, social capital has been explored in various ways, including interactions with neighbors (e.g., Elder et al., 2012) and links with farmer organizations (e.g., Uphoff and Wijayaratna, 2000). In this study, the assessment of social capital focuses on relations between Soppexcca members, the cooperative itself, and transactions with other coffee buyers, with special attention to the formation of mutually beneficial trading relationships. The data collected focused on the services and inputs received by smallholders from buyers, and, in the case of Soppexcca, the ability of the cooperative to service, and source raw material from, its members.

Environmental sustainability issues were addressed under the management of natural asset – soil fertility – and human asset – waste management practices. Commercial sustainability was subsumed within concepts of social and financial capital. Equity issues, such as differential impacts and outcomes for households, were addressed through the clustering approach.
In addition to information on assets, data were collected on other major income sources, on contextual factors that could have facilitated or hindered asset building, and members’ insights into the reasons why a given change did or did not take place.

The sample included 292 coffee-producing households – about 95% of the membership of 11 of Soppexcca’s 18 base cooperatives. Criteria for base cooperative selection included distance from Soppexcca’s headquarters and geographical concentration of members in a given base cooperative. To facilitate data collection, preference was given to those cooperatives with a higher concentration of households. Unless otherwise indicated, coffee quantities are presented as pre-dried parchment coffee – the semi-processed state of coffee when it is sold by producers to buyers such as Soppexcca. One hundred pounds of export-ready (green) coffee is commonly processed from roughly 200 lb of pre-dried parchment coffee produced by farmers in north-central Nicaragua.

Data collection was conducted in Jinotega and Matagalpa districts during a nine-month period in 2009–2010. Primary data from household surveys and key informant interviews were supplemented by secondary information from Soppexcca staff. Twenty key informant interviews were conducted with Soppexcca leaders, international coffee buyers, certification agents, and other chain actors. Recall information was used to identify current asset endowments and changes in asset endowments over the assessment period.

Cluster analysis allowed for understanding the potential for asset building by different types of households. Clusters were formulated using a two-step clustering technique using SPSS. Two variables with strong correlation that formed the basis for formation of the clusters were (1) area under coffee production in 2008–2009 and (2) percentage of total household income derived from off-farm sources in 2008. A three-cluster solution emerged from this analysis, with household livelihoods descriptors and cluster characterization as follows:

- **Small-scale diversified livelihoods (SDL)** (n = 77): relatively small area under coffee production; high dependence on income derived from off-farm labor activities (often as wage labor for other, usually larger farmers); some contribution from other crops.
- **Small-scale specialized livelihoods (SSL)** (n = 162): relatively small area under coffee production; majority of income derived from farm, with contributions from banana, citrus, beans and other products.
- **Large-scale specialized livelihoods (LSL)** (n = 53): relatively large area under coffee production; majority of income derived from coffee, with contributions from livestock, banana, citrus and other products.

Table 1 provides insights into the differences between the clusters. The mean total annual income for the sample was US$4969 (or, given an average household size of 5.2, US$956 per capita). Pushing up the average was total income for LSL households, which at US$14,627 was several-fold higher than that of other households. For both LSL and SSL households, coffee contributed between 85% and 93% of total income. For SDL households, coffee contributed approximately 33% of total income, with 5% coming from other farming activities and 62% from off-farm. In most cases, these households depended on short-term, low-skill jobs in the agricultural sector. Across all the clusters, cash income derived from agricultural sources other than coffee was generally a small share of total income. The ANOVA results suggest that the cluster solution was robust and thus provided a solid basis for analysis of changes in livelihood assets.

### Changes in assets of coffee producing households

#### Natural capital

**Access to land and area under coffee production**

The expansion of landholdings and the area under coffee production provide important indicators of natural capital management and the overall ability of smallholders to improve their well-being through access to specialty coffee markets. For both indicators, results suggest a notable improvement in natural capital for a broad section of the sample. Eighty households, or nearly one-third of the sample, expanded their landholdings. The average landholding increased from 4.6 ha to 5.1 ha (Fig. 2). Among the clusters, the largest percentage increase in landholdings, at 15.4%, was recorded by households from the SDL cluster. Households from the SSL cluster increased their landholdings, on average, by 11.8%, while, on average, households from the LSL cluster experienced limited change in landholdings.

Many households also increased their area under coffee production through new land purchases or the conversion of existing land to coffee production. Roughly half the sample, or 158 households, expanded coffee production. The average area increased from 1.9 ha to 2.5 ha (Fig. 3). Households from the LSL cluster increased area under coffee, on average, by 1.4 ha (28% increase over the pre-existing area). Households from the SSL cluster increased area under coffee, on average, by 0.4 ha (31% increase over the pre-existing area), while households from the SDL cluster increased their area under coffee by an average of 0.29 ha (26% increase over the pre-existing area).

Expansion of landholdings and area under coffee represent considerable investments over multiple years. Households often

<tr>
<th>Land-tenure arrangements</th>
</tr>
</thead>
</table>
| Land-tenure insecurity is a legacy of the agrarian reform, which left many potential coffee farmers in ambiguous legal positions regarding land ownership, vulnerable to appropriation of land titles by banks. This situation has long challenged rural development in Nicaragua (Broegaard, 2005; Fraser et al., 2013). For some Soppexcca-affiliated households, uncertain tenure arrangements prior to joining the cooperative severely restricted investments in farm production. These households belonged to two Soppexcca-affiliated base cooperatives, which, when combined, formed roughly one-third of the SDL cluster. For members of one of these two base cooperatives, Julio Hernández, considerable progress was achieved in building natural capital and other assets during the period. However, for members of the base cooperative El Esfuerzo, insecure tenure persisted and would likely constrain their investments in coffee for the distant future. The cooperative Julio Hernández illustrates key points in asset management and building. Prior to 2001, the members lived and worked on a state-owned coffee enterprise. In 2001, a collective title was obtained for the plantation, and soon after, individual plots were distributed among the former plantation workers. With individual plots came the urgent need for members to build skills in coffee production, renovate coffee plantations, and link with coffee buyers. Soppexcca facilitated the organization of the base cooperative and provided technical assistance and credit for coffee reclamation. Productivity levels for Julio Hernández members increased significantly during the period, from a two-year average of 314 kg/ha in 2004–2005 and 2005–2006 to 503 kg/ha in 2008–2009 and 2007–2008. Anecdotal evidence suggested that the advances in productivity were linked to services provided by Soppexcca: pre-existing assets among members were relatively low and no other provider of technical assistance or credit was identified during the period. Moreover, Julio Hernández members emphasized the role of Soppexca in building their natural and financial capitals during interviews. However, the case of El Esfuerzo illustrates the vulnerability of households where members had yet to overcome power abuse and conflict related to land tenure. During the 1990s, the households that would form El Esfuerzo farmed collectively titled land and sold their coffee through a collective enterprise. The coffee was sold to an exporter who provided credit in exchange for a set amount of green coffee. In 1999, the exporter failed to provide credit, and households struggled to collect sufficient coffee to meet their delivery quota. In response, the exporter took possession of their land. The households retained a lawyer and fought the case for nine years before achieving success. Currently, the lawyer holds the collective land title and will release it to the households when she is paid the US$80,000 owed for her services. By 2009, El Esfuerzo members continued to rank among the least productive coffee farmers and were among the least able to sustain their livelihoods through on-farm production. Access to fertilizers (proxy for soil fertility) Coffee production mines nutrients from the soil, which, if not replaced through organic or inorganic fertilizers, results in gradually declining productivity (Van der Vossen, 2005). Thus, use of fertilizers and maintenance of soil fertility are key indicators of resource management and sustainability. Evidence from long-term investments in coffee for the distant future.
Human capital

Management skills in coffee production

One important element of human capital for coffee growers is the knowledge, skills and capacity to manage plantations sustainably and produce uniform, high quality beans. In general, smallholders in Nicaragua do not practice regular pruning or other forms of improved crop management on their coffee plantations (Rice, 1999). This, combined with knowledge that several of Soppexca’s base cooperatives had only recently gained land titles and thus the opportunity to invest in their coffee production, suggests that overall human capital endowments in this context were low prior to the period. Before joining Soppexca, most interviewed households reported not having access to technical assistance for coffee production. Technical assistance and training by Soppexca in shade management and pruning techniques aimed to support their members to sustain coffee yields, while at the same time enhancing natural capital (e.g., reduced contamination, protection from erosion, and enhanced nutrient recycling).

Results among the sample were mixed. On one hand, most households acquired new skills for reducing contamination from coffee milling and providing higher-quality coffee. Fifty-four per cent of the households reported the application of selective harvesting (of mature beans) during the period. Most of these households were from the SSL cluster (n = 31) and the LSL cluster (n = 12). Six households from the SDL cluster reported the implementation of selective harvesting. Similarly, 66% of the households disposed of wastewater in infiltration pits in 2008–2009 (compared to only 11% of the sample three years prior). SSL households were the most likely to have adapted the new techniques for wastewater treatment (74%), followed by LSL households (70%) and SDL households (58%).

The overall low coffee productivity suggests that improper plantation management may continue to be a genuine concern. While it was not possible to observe or measure plantation management practices for this study, insights were gained on the effectiveness of technical assistance through interviews with technical assistance staff and from Soppexca members. The evidence suggests that Soppexca’s technical assistance program struggled to provide the coverage and quality of services needed for upgrading the production skills of poor coffee farmers. According to one key informant, efforts to encourage more intensive plantation management have been ineffective, due in part to (1) a reluctance by producers to trim or stump coffee trees that are productive and (2) the inability of Soppexca staff to work intensively with producers to upgrade their crop management skills (Pinedo, 2009). Soppexca had yet to implement a monitoring system for plantation management. Moreover, there was no link between Soppexca technical assistance and the credit department.

Households reported their perceptions on the value of technical assistance for coffee production between 2007–2008 and 2008–2009. For most households, Soppexca was the only provider of training and on-site technical assistance. Forty-four per cent (n = 129) reported being dissatisfied or highly dissatisfied with technical assistance provision. Selected household responses shed light on the nature of the problem:

- **Household #26**: “We were visited once in 2008, but the extensionist didn’t provide technical advice; he arrived to inform us of a meeting at the cooperative.”
- **Household #265**: “I lack advice when I need it: on one occasion, I requested a visit from the extensionist because the coffee berries were falling off the branches, but he never came.”
- **Household #187**: “He only comes to estimate the harvest. I am only able to consult with the extensionist during training events—that is how I have obtained technical assistance.”
- **Household #277**: “Visits are only for estimating the harvest—the extensionist does not know my coffee plantation. He sends others from the community to assist me and does not provide advice.”

---

1 To achieve reasonable yields from organic coffee production in Nicaragua, Haggar et al. (2011) reported the use of nearly 9 tons of coffee pulp per ha/yr. This is roughly two to three times as much pulp as just returning the pulp from the coffee produced.

2 To keep coffee yields at a reasonable level and to maintain soil fertility, a minimum of 36 kg of nitrogen/ha need to be supplied annually (Valkila, 2009). This assumes that producers recycle their coffee pulp and use nitrogen-fixing shade trees – both of which are common practices among smallholders in Nicaragua.
Characteristics of trading relationships for coffee sold by Soppexcca members.

<sup>a</sup> Information based on results from 18 key informant interviews carried out on-site with buyers of coffee at the markets of Jinotega and Matagalpa in August 2009.

<sup>b</sup> For example, emergency transport to hospital, contributions to meeting funeral expenses, assessment with land tenure disputes.

- **Household #282:** “Sometimes he indicated which product I should use, but the extensionist did not indicate the doses and I burned the plants.”

**Skills for cooperative governance**

A share in ownership and governance by members is an important cooperative principle and feature of human capital. Findings showed that representation of members on the board of directors was mostly tokenism. The main reasons were insufficient skills by the board and lack of information from Soppexcca. The former president of the board noted that she received no training in basic business or in cooperative management prior to assuming her post as the board president. During her period on the board she had limited understanding of how Soppexcca formulated its prices for parchment coffee, nor did she participate in setting the agenda for board meetings. Other informants noted that the board and Oversight Committee did not have access to timely financial information, due mainly to the absolute lack of the information, rather than inaccessibility of the information. Interviews highlighted the board’s reluctance to question, debate, or probe Soppexcca’s executive management in strategic decisions and investments. External service providers remained distant on the empowerment of Soppexcca’s members and engaged directly with Soppexcca’s professional management.

Strong professional leadership, combined with a long-term commitment from buyers and NGOs to its development and the institutional framework provided by fair-trade certification has played an important role in building Soppexcca’s organizational asset base, but this has come through external investment rather than organic human capital growth among the membership. Limitations to build effective internal leadership within the cooperative has resulted in a high concentration of power and information in the professional manager, hence vulnerability of the organization and all the value chain relationships.

**Social capital**

From an individual or household perspective, the extent to which linkages with coffee buyers generate tangible benefits for maintaining and improving livelihoods forms an important element of social capital (Portes, 1998). Our discussion of social capital focuses on the supply-chain relationship benefits derived from collaboration with Soppexcca and the significance of institutional arrangements for reducing transaction costs.

In general, smallholders rarely have access to affordable credit in Nicaragua (Bastiaensen, 2005). Prior to joining Soppexcca, most households from the SDL and SSL clusters (69% and 67%, respectively) sold their coffee exclusively to buyers in the towns of Jinotega and Matagalpa. In contrast, only 36% of households from the LSL employed intermediaries for marketing their coffee prior to joining Soppexcca. Few households reported access to buyer-provided credit in the year prior to joining Soppexcca (20%) and even fewer reported access to buyer-provided technical assistance (9%). Households from the LSL cluster were more likely to have forged linkages with direct exporters prior to their having joined Soppexcca, and thus were more likely have access to credit and higher prices.

Having forged new linkages with Soppexcca, most households retained their previous relationships with pre-existing coffee buyers. Buyers differed in terms of services offered and the transaction costs of doing business (Table 3). Relative to other buyers, Soppexcca was the most demanding in terms of quality but also offered the most extensive range of services. In 2008–2009, credit was available for most members without formal land titles or other forms of collateral at an annual interest of 16% for annual credit and 14% for multiyear credit. Soppexcca was the only buyer that offered protection from future downturns in coffee prices through the fair-trade floor price.

Soppexcca provided other valuable services. Beginning in 2007, the cooperative employed a team of eight extensionists to provide...
technical assistance. In addition, Soppexcca provided safety nets for its members (vehicular transport for emergencies, donation of a coffin on the death of a member or member’s spouse, credit/donations for medical expenses), and access to development projects. However, doing business with Soppexcca was relatively costly. Payment for coffee was made in three installments, with final installment (approximately 20% of the total price) being delayed until May–June. All credit and payment transactions required travel to Soppexcca’s office in Jinotega and producers assumed all risks for transport of coffee to the warehouse.

Compared to Soppexcca, transactions with market buyers offered faster payment, with cash upon delivery of coffee and credit on demand; however, producers had to trade off ease of sale and timeliness of payment against generally slower business processes and higher costs for credit.

Few sampled households sold to direct exporters of coffee \( (n = 5) \). Exporters provided annual credit on a contract basis, with land titles generally required as collateral unless producers had a history of compliance with contractual obligations. Annual credit during the 2008–2009 season was offered at a 17% annual interest rate. Producers had the option to receive final payment (market price minus amount of annual credit) upon delivery of parchment coffee. Additional services, such as on-site technical assistance and pick-up of parchment coffee, were not reported.

Side-selling is a common but complex phenomenon affecting cooperative operations and relationships with members. Data on coffee sales by buyer indicated Soppexcca’s difficulty in increasing its capture of raw material from its members. For organically certified households, the mean percentage of coffee sold to Soppexcca between 2007–2008 and 2008–2009 was 73%, while for conventional producers, the mean percentage was 57% (Table 4). This suggests that price was not the major factor behind selling to buyers other than Soppexcca. Responses presented below illustrate the diversity of reasons. The most common response hinged on the need to cover production expenses for the coffee harvest (n = 31). In other cases, households identified emergencies and expenses (n = 8), poor quality (n = 4), and restricted access to credit (n = 2). Below are quotes from households in SDL cluster (emphasis added):

- **Household #190**: “Don Osman pays better than Soppexcca; Soppexcca has too many price deductions, and he is less concerned with quality.”
- **Household #24**: “Because my brother needed money, I sold coffee in the market to resolve his need.”
- **Household #188**: “Due to delays in the provision of credit—the intermediary is much quicker. Soppexcca always delivers credit in June, while the intermediary delivers in May.”

### Physical capital

**Capital for processing**

Improvements in infrastructure at the household level played a major role in Soppexcca’s strategy for improving coffee quality. Physical capital for wet milling includes the construction/refurbishment of mill enclosures, construction/refurbishment of fermenting tanks, and the purchase/repair of machines for depulping and pumping water. Table 6 provides clusterwise details of household expenditures. The average investment by households from the SDL cluster was US$198 during the period, skewed upwards by a few households; among the 72 households in the cluster, only 12 reported cash investments for improved wet milling. Investments by SSL, while significantly higher than those of the SDL cluster, remained low at US$593. Moreover, 70 SSL households, or nearly half the cluster, reported no cash investments during the period. Investments by LSL households, at nearly three times those of SSL households, showed considerably less variation within the cluster. Credit by Soppexcca contributed roughly 48% of the total reported household expenditure.

### Capital for production

Households also reported their acquisition of machinery, tools, and infrastructure for agricultural production in addition to those used for wet milling. Notable is the extremely low investment by households in the SDL cluster, at US$91 (Fig. 4). When investments were made by SDL households, they were generally confined to basic tools for production of coffee and basic grains (machetes, shovels, and sprayers). Similar to experiences in the building of physical capital for wet milling, households in the SSL cluster achieved higher investments than their SDL counterparts, but the absolute level of investments was low. In general, findings suggest that households from SDL and SSL clusters struggled to build their physical capital endowments for farm production compared to the level of productive investments made by LSL households. These included relatively large purchases of machinery for the production of coffee, investment in livestock, and generation of off-farm business activities.

### Financial capital

**Access to credit**

The ability of households to build natural and physical capital was strongly related to their access to multiyear credit. Between
2004–2005 and 2008–2009, 56% of the sample, or 164 households, received credit for the purchase of land or expansion of coffee production. SDL households (36%) were the least likely to have received access to multiyear credit during the period, compared to SSL households (65%) and LSL households (58%). The average amount of credit was US$1271. Among the clusters, the average amount varied from a low of US$889 for households in the SSL cluster to a high of nearly US$1319 for households in the SLS cluster. Among households in the SDL cluster, an average of US$957 in credit was received, all of which Soppexcca provided.

As noted previously, many sampled households (57%) reported no access to annual credit prior to joining Soppexcca. During the assessment period, opportunities for obtaining annual credit increased, in part due to linkages with Soppexcca, with only 12% of sampled households reporting no access to annual credit. Among the households that received annual credit, most (n = 160, 55%) reported Soppexcca as their only source of credit. Other sources included specialized lending organizations, coffee buyers, NGOs, and, to a lesser extent, informal lenders and commercial banks. Collateral requirements varied.

While the terms offered by Soppexcca were relatively favorable, the average amount provided by Soppexcca was small. For example, in 2007–2008, the mean credit value for SDL household was US$197, US$390 for SSL households, and US$1805 for LSL households. Even for households with relatively small coffee holdings, credit from Soppexcca was unlikely to cover variable production costs, much less facilitate more strategic investments in asset building. Moreover, few households were able to access credit consistently: only 9.3%, 11.3%, and 25% of the SDL, SSL, and LSL households, respectively, were able to access annual credit for each year of the assessment period. Between 20% and 55% of SDL households ended the production year with debt to Soppexcca, with similar results recorded for SSL households.

**Income benefit from coffee sales to Soppexcca**

Findings about benefits of coffee sales through Soppexcca are illuminating. As noted above, it is not uncommon for smallholders to divert sales from formal to informal channels. Table 5 presents estimates of the income benefit for Soppexcca members from coffee sales, taking into account sales to Soppexcca and to other buyers and allowing for the differences in farm-gate prices between coffee buyers. Among households from SDL and SSL clusters that produced conventional coffee, the actual income benefits from participation in Soppexcca were small, at US$32 and US$87, respectively. These income estimates reflect that 41%-45% of the potential income benefit from the sale of fair trade coffee was lost due to the selling of coffee to other buyers. Certified-organic households from the SDL and SSL clusters experienced higher income benefits than their conventional counterparts, at US$77 and US$94, respectively. However, these households also struggled to maximize their income benefits from participation in formal markets. On average, 27% of the total potential income benefit from the sale of fair trade organic coffee was lost due to the selling of coffee to other buyers. For producers of conventional coffee, the small size of the price benefit generated through sale of coffee to Soppexcca may have facilitated their decision to sell to other buyers. For both types of producers, the strong need to sell coffee outside of Soppexcca often reflected farmers’ urgent needs for annual credit linked to coffee production, for the ability to respond to shocks, and to smooth income generation over the year.

**Discussion**

For poor smallholder coffee growers, research has highlighted both the potential and the limitations of asset building by coffee growers in Nicaragua in response to more intensive value chain interactions and development interventions. Our discussion begins with a look at the overall changes in asset endowments and then examines the differences in asset building based on cluster affiliation.

Many households built up key elements of natural capital, including expanded areas under coffee production and renovated coffee trees. These investments helped to overcome the erosion of natural capital that took place during the coffee crisis. For households that depend on coffee production for most of their income, these investments are likely to have positive future impacts on rural livelihoods. Access to credit with extended repayment periods played a critical role in expanding and improving natural capital. On the other hand, lack of progress in addressing other dimensions of natural capital, such as nutrient mining due to lack of affordable fertilizers and insecure land tenure, are likely to diminish hopes that poor households will improve their coffee productivity in the future.

A similar pattern of significant, but incomplete, asset building was detected for the other capitals. In terms of human capital, evidence suggests that most households acquired new skills that improved coffee quality, but few households had acquired the more complex skills for improved plantation management – a critical determinant of coffee productivity and disease resistance. The ability to implement more intensive production practices was also linked to endowments of human and financial capitals, which were also severely constrained in many cases.

Results suggest that there were limited impacts to build human capital through cooperative-provided technical assistance.

</table>
Soppexcca had no monitoring system in place nor had it attempted to link technical assistance with its other services (e.g., credit) or external services (e.g., specialized providers of business development and technical services). Donors, projects, and NGOs that financed technical assistance by Soppexcca were reluctant to insist on accountability or engage Soppexcca in identifying outcome-enhancing measures.

Results also draw attention to challenges faced by Soppexcca’s volunteer leadership to effectively participate in Soppexcca’s governance. Volunteer leaders lacked basic business skills prior to assuming their posts, as well as access to critical information on business performance. They indicated apprehension about confronting authority, and conflicts emerged among members when professional managers were questioned. Reluctance to challenge the management was likely enhanced by the failure of Soppexcca’s predecessor cooperative, juxtaposed with its success in expanding sales of certified coffee and securing support from NGOs and projects. Results here support previous findings on the autocratic nature of cooperative governance in Nicaragua and the distant engagement of NGOs in the development process (Kroeker, 1996).

Links to Soppexcca and markets for certified coffee resulted in an important increase in social capital for households. Soppexcca offered some protection from the recurrent economic, social, and environmental uncertainties that characterize coffee production in Nicaragua. Technical assistance and credit allowed households to rebuild assets that were eroded during the coffee crisis. For many households, Soppexcca offered the first opportunity to access credit and technical assistance since they initiated coffee production. Despite the importance of links to Soppexcca, most households diverted considerable quantities of coffee to local intermediaries or direct exporters. Mujawamariya et al. (2013) suggest that smallholders’ decisions to deal with buyers outside the cooperative likely responds to their trust relations within local buyers based on repeated transactions in credit. Evidence from Soppexcca supports this argument. The use of credit for meeting consumption needs, combined with the relatively high costs of selling to Soppexcca (e.g., high quality demands, delayed payment, and transport to warehouse) also encouraged side selling by Soppexcca members. Households managed a portfolio of buyer relationships in such a way as to optimize the relationship between product prices and production, access to credit and transaction costs of and sales.

In general, households struggled to build physical capital for agricultural production, in general, and coffee production, in particular. The general expansion of wet-milling infrastructure and equipment was one element of physical capital where considerable investments were detected. Multiyear credit by Soppexcca facilitated these investments. The credit was provided to Soppexcca by NGOs looking to support the cooperative in its efforts to enhanced coffee quality and reduce water consumption and contamination in the processing of coffee cherries.

The income benefits from access to certified-coffee markets were generally limited during the period under assessment, reflecting the high prices of conventional coffee relative to those for certified coffee. At the time of data collection (2009–2010), international commodity prices for coffee were higher than at any period in the past 20 years. However, boom and bust are recurrent features of coffee markets, suggesting that a future analysis of income benefits from another crisis would present strikingly different findings. Indeed, Soppexcca’s initial growth occurred before the period of this study when the price premium for certified coffee was very attractive to smallholders struggling with the aftermath of the coffee crisis. Despite relatively small income benefits, engagement with the cooperative was important for other reasons: access to credit facilitated coffee production and provided a form of insurance against shocks such as illness, death, and crop failures, which otherwise would have resulted in asset erosion. While many households received credit for coffee production for the first time through Soppexcca, access to credit was often inconsistent and the amount of credit was insufficient to intensify coffee production or make longer-term strategic investments in asset building.

This study offers a cautious but positive view on the potential of poor smallholders to improve livelihood security through links to cooperatives and higher value coffee markets. Feasibility constraints limited the chosen set of indicators of livelihoods assets, but the most significant changes have been captured. Improvements in natural, social, and financial capital ensured that households had the minimum endowments needed to participate in the Soppexcca value chain. Access to Soppexcca offered safety nets, lower marketing risks, and access to inputs, which have important positive implications for livelihood maintenance and security. On the other hand, there was little evidence that interventions by the cooperative and its NGO and donor partners allowed households to intensify production or to generate new products and services outside of the coffee value chain. The extent to which potentially greater gains in livelihood security could have been achieved through physical capital expansion aimed at increased efficiency and productivity of other crops, such as bananas, beans, and corn, remains to be explored by Soppexcca and its external partners. Thus complex business skills remained undeveloped. This may be explained by the incomplete nature of asset building during the assessment period, the overall weak household asset endowments prior to the assessment period, and the time it takes to develop individual human and collective social capital.

**Heterogeneity in asset building**

Significant variation due to pre-existing endowments was evident in the ability of households to build assets. Table 6 summarizes and compares asset building between the three clusters. In general, SDL households were the least likely to have achieved major advances in asset building. This was especially true in terms of human, physical, and financial capitals. SDL households benefited from certified-coffee markets mainly through access to Soppexcca safety nets and reduced vulnerability to external shocks. The experiences of SDL households that seem to fall below a responsiveness threshold showed that rural poverty goals might best be achieved by helping those households with the smallest asset endowments to transition out of agriculture. SSL households experienced altogether greater gains in asset building and the gains were more evenly spread across the different types of capitals. Nevertheless, the better-endowed LSL households were the primary beneficiaries in terms of financial capital and most of the other areas of asset building.

**Conclusions**

This study applies a livelihoods asset framework to understand smallholder assets building in response to new links with a coffee cooperative that enabled participation in high-value certified-coffee markets. Embedded in these links were a set of interactions, interventions, and processes that shaped how smallholders participate in the value chain. This use of a livelihoods asset framework
marks a conceptual and methodological contribution to the literature through its exploration of how households are able benefit from new links to markets, the differences in household participation based on variations in livelihood strategies and initial asset endowments, and the role of cooperatives and development interventions in creating important linkages between producers and international markets.

How did initial asset endowments and subsequent household changes determine smallholders’ participation in high-value export markets? In short, did the access to certified-coffee markets help the poorest? The analysis presented here suggests that the institutions, interventions, and processes related to participation in certified-coffee markets did achieve a broader set of outcomes than merely accessing favorable prices, including building a sustainable and more competitive value chain, the building of more viable cooperatives, and building of specific assets by some of the poorest farming households. It was shown that all of these outcomes were important to creating a viable coffee value chain providing some livelihood improvements and even a pathway out of poverty for many of the households linked to it.

However, even a cursory examination of Table 6 shows that those with better initial asset endowments (i.e., the LSL households) gained the most from the interventions and new opportunities accessed through Soppexcca. This conclusion, together with the evidence that the least well-endowed experienced the least asset-building in absolute terms, suggests that a multiple threshold concept of asset endowments is likely to operate: that is to say, there are likely to be multiple thresholds, such as an upper threshold above which the better-off producers benefit little, an intermediate threshold above which producers can take advantage of the opportunities, and possibly a lower threshold below which the poorest may experience asset depletion resulting from development interventions that increase risk and vulnerability (Donovan and Poole, 2013). The Soppexcca experience also shows that achievements do not come cheaply or quickly: they result from years of investments by coffee buyers, donors, and civil society, Soppexcca, and cooperative members.

Conclusions on economic and environmental sustainability are tentative, because sustainability was not the focus of the study and changes will only be demonstrated over the long term.

This study – even using a reduced set of livelihood asset indicators – highlights the challenges and dilemmas for poverty-reduction policies based on more intensive links to higher-value markets. It suggests a development strategy that recognizes the complexities and trade-offs among asset types that are by no means discrete, but often are complementary and sometimes antagonistic. The study highlights the important role that cooperatives play in building the capacities of the poor to participate in higher-value markets. It also suggests that cooperatives will benefit from greater attention to the consolidation of their internal governance mechanisms, as well as support in the design, implementation, and monitoring of cooperative-provided services. Finding viable solutions to the complex problems facing cooperatives and their members will require deeper engagement with stakeholders, including NGOs, buyers, and government agencies.

There are additional lessons: first, the notion of asset complementarities. For example, a clear conception of financial capital is important. Financial capital is more than income or credit access through Soppexcca. This conclusion, together with the evidence that the least well-endowed experienced the least asset-building in absolute terms, suggests that a multiple threshold concept of asset endowments is likely to operate: that is to say, there are likely to be multiple thresholds, such as an upper threshold above which the better-off producers benefit little, an intermediate threshold above which producers can take advantage of the opportunities, and possibly a lower threshold below which the poorest may experience asset depletion resulting from development interventions that increase risk and vulnerability (Donovan and Poole, 2013). The Soppexcca experience also shows that achievements do not come cheaply or quickly: they result from years of investments by coffee buyers, donors, and civil society, Soppexcca, and cooperative members.

Conclusions on economic and environmental sustainability are tentative, because sustainability was not the focus of the study and changes will only be demonstrated over the long term.

This study – even using a reduced set of livelihood asset indicators – highlights the challenges and dilemmas for poverty-reduction policies based on more intensive links to higher-value markets. It suggests a development strategy that recognizes the complexities and trade-offs among asset types that are by no means discrete, but often are complementary and sometimes antagonistic. The study highlights the important role that cooperatives play in building the capacities of the poor to participate in higher-value markets. It also suggests that cooperatives will benefit from greater attention to the consolidation of their internal governance mechanisms, as well as support in the design, implementation, and monitoring of cooperative-provided services. Finding viable solutions to the complex problems facing cooperatives and their members will require deeper engagement with stakeholders, including NGOs, buyers, and government agencies.

There are additional lessons: first, the notion of asset complementarities. For example, a clear conception of financial capital is important. Financial capital is more than income or credit arrangements. Working financial capital underpins investment in other livelihood assets, particularly natural and physical, such as fertilizer (for maintaining natural capital) and agricultural equipment and roofing (for physical capital). It is also an important entitlement mechanism to meet general household expenses and other human capital-building pathways such as educational expenses for children. Thus financial capital has two important characteristics: it is a means to an end rather than an end in itself; and it is fungible: actually it is a means to various ends. But while the provision of credit is of primary importance, it is not a panacea. Other complementarities exist: contextual or idiosyncratic household constraints affect the capacity of smallholders to take advantage of new opportunities, for example, labor constraints that inhibit physical expansion of farms as well as the adoption of improved management practices. Investments involve strategic choices and often significant trade-offs between diverse livelihood activities, as well as risk of asset depletion: livelihood losses. For broader social objectives, interventions required will be more complex and involve a range of services that take into account asset trade-offs, particularly among the poorest. Heterogeneity and complexity thus make intervention targeting a serious ethical necessity.

Second, because of complementarities and trade-offs, projects and interventions must not merely address the weakest links in the chain, through interventions directly targeting specific weaknesses such as the provision of finance or of technical assistance. Programmes and policies must reflect a more holistic approach to value chain enhancement, specifically addressing the underlying constraints and capacities of smallholders: land tenure, credit collateral, small scale, labor constraints, technological change, principles and practice of cooperative action, and enhancement of business skills, all within a framework of environmental, social, and economic sustainability.
